Abstract

The previously developed renormalizable perturbative $1/N$ -expansion in higher dimensional scalar field theories is extended to gauge theories with fermions. It is based on the $1/N_f$ -expansion and results in a logarithmically divergent perturbation theory in arbitrary high odd space-time dimension. Due to the self-interaction of non-Abelian fields the proposed recipe requires some modification which, however, does not change the main results. The new effective coupling is dimensionless and is running in accordance with the usual RG equations. The corresponding beta function is calculated in the leading order and is nonpolynomial in effective coupling. The original dimensionful gauge coupling plays a role of mass and is also logarithmically renormalized. Comments on the unitarity of the resulting theory are given.

1 Introduction

In our previous paper [1] (hereafter [I]) we constructed renormalizable perturbative $1/N$ expansion in scalar field theories in higher dimensions. It was demonstrated that the $1/N$ expansion¹ contrary to the usual perturbation theory is renormalizable [5, 6], leads to a finite number of logarithmically divergent terms and can be made finite by renormalization of the fields and a new dimensionless coupling. The original dimensionful

¹for review of the $1/N$ expansion see [2, 3, 4]

coupling does not serve as an expansion parameter anymore and plays the role of mass which is also logarithmically divergent and multiplicatively renormalized. Within the dimensional regularization technique [7] we performed the renormalization procedure in scalar theories in arbitrary odd space-time dimension and calculated a few terms of the $1/N$ expansion. Even dimensions, in principle, can also be treated by this method; however, they lead to some complications due to the appearance of log terms. We did not consider them in [I] and do not do it here.

The main recipe of the $1/N$ expansion is the following (see for example [8]): one considers a theory with an N -component field interacting with some real or auxiliary singlet field and calculates the propagator of this singlet field. If one divides the coupling of their interaction by $\sqrt{N}$, then any simple virtual loop in this propagator is suppressed by a factor of $1/N$ which is cancelled by an opposite factor coming from the closed loop of the N -component field. Thus, each of this bubbles has no $1/N$ suppression and in the leading order one has to sum them up. The resulting "zeroth" order propagator contains the polarization operator, which is an increasing function of momenta, in the denominator. This new propagator has to be used now in all Feynman diagrams order by order in $1/N$. Since it decreases faster than the usual one, it improves the convergence of the integrals and leads to logarithmically divergent diagrams even in arbitrary high extra dimensions.

The aim of this paper is to demonstrate how the advocated procedure works in gauge theories which contain some peculiarities due to the gauge invariance. We show that indeed in the case of an Abelian theory the procedure is straightforward while in the non-Abelian case it needs some modification due to the presence of the triple and quartic interactions of gauge fields.

When summing up the vacuum polarization diagrams to the denominator, one faces the problem of unitarity due to the presence of the imaginary part in the polarization operator and possible poles in the complex plane. This problem is common to any realization of the $1/N$ expansion and deserves a special treatment [6, 9]. We briefly comment on this problem below.

2 QED

Let us start with the usual QED with N_f fermion fields in D dimensions, where D takes an arbitrary odd value. The Lagrangian looks like

$$\mathcal{L} = -\frac{1}{4}(\partial_\mu A_\nu - \partial_\nu A_\mu)^2 - \frac{1}{2\alpha}(\partial_\mu A_\mu)^2 + i\bar{\psi}_i \hat{\partial} \psi_i - m\bar{\psi}_i \psi_i + \frac{e}{\sqrt{N_f}}\bar{\psi}_i \hat{A} \psi_i. \quad (1)$$

According to the general strategy, we now have to consider the photon propagator. Since due to the gauge invariance the polarization operator is transverse, it is useful to consider a transverse (Landau) gauge. This is not necessary but simplifies the calculations. Then in the leading order of the $1/N$ expansion one has the following sequence of bubbles (see Fig.1)

Figure 1: The chain of diagrams giving a contribution to the A field propagator in the zeroth order of the $1/N_f$ expansion

summed up into a geometrical progression. The resulting photon propagator takes the form similar to that for an auxiliary σ field in [I]

$$D_{\mu\nu}(p) = -\frac{i}{p^2} \left(g^{\mu\nu} - \frac{p^\mu p^\nu}{p^2} \right) \frac{1}{1 + e^2 f(D) (-p^2)^{D/2-2}}, \quad (2)$$

where

$$f(D) = \frac{\Gamma^2(D/2)\Gamma(2-D/2)}{2^{[D/2]-1}\Gamma(D)\pi^{D/2}}$$

and we put $m = 0$ for simplicity.

This practically coincides with the expression obtained in scalar theory and all the following steps just repeat those in the latter. As was explained in [I], we change the normalization of the gauge field $A_\mu \rightarrow A_\mu/e$ and introduce the dimensionless coupling h associated with the triple vertex, so the effective Lagrangian takes the form

$$\begin{aligned} \mathcal{L}_{eff} = & -\frac{1}{4}F_{\mu\nu} \left(\frac{1}{e^2} + f(D)(\partial^2)^{D/2-2}(1+h) \right) F_{\mu\nu} - \frac{1}{2\alpha e^2}(\partial_\mu A_\mu)^2 \\ & + i\bar{\psi}_i \hat{\partial} \psi_i - m\bar{\psi}_i \psi_i + \frac{\sqrt{h}}{\sqrt{N_f}} \bar{\psi}_i \hat{A} \psi_i. \end{aligned} \quad (3)$$

This new dimensionless coupling h enters into the gauge transformation and plays the role of a gauge charge. The old coupling e , on the contrary, is dimensionful and acts as a mass parameter in a gauge propagator. Since the coupling constant h is dimensionless the effective Lagrangian (3) when omitting the first term is conformal as considered in [10] where the theory was taken in $D = 3$.

Again, one has the modified Feynman rules with the photon propagator that decreases in the Euclidean region like $1/(p^2)^{D/2-1}$, thus improving the UV behaviour in a theory. The only divergent graphs are those of the fermion propagator and the triple vertex. They are both logarithmically divergent for any odd D . The photon propagator is genuinely finite and may contain divergencies only in subgraphs. One basically has the same graphs as in [I] for a scalar theory but with solid lines being the fermion ones and the dashed lines being the photon one.

The only difference (or simplification) comes from the Furry theorem and the gauge invariance. Namely, all triangles with three photon external lines vanish due to the Furry theorem and the gauge invariance which connects the fermion propagator with the triple vertex implies that $Z_1 = Z_2$. This relation holds in the $1/N_f$ expansion like in the usual PT. Thus, using the notation of [I], in the leading order one has

$$A = -\frac{\Gamma(D)(D-1)(2-D/2)}{2^{D/2}\Gamma(2-D/2)\Gamma(D/2+1)\Gamma^2(D/2)}, \quad B = -A, \quad C = 0. \quad (4)$$

The same results were obtained in [11] where the author calculated the anomalous dimensions at the d-dimensional critical point where the fields obey asymptotic scaling and are conformal. This leads to the following renormalization constants in the leading order in $1/N_f$:

$$Z_1 = Z_2 = 1 + \frac{1}{\varepsilon N_f} \frac{Ah}{(1+h)}, \quad Z_3 = 1 \quad (5)$$

and, consequently, $h_B = h$. Hence, in odd-dimensional QED in the leading order of the $1/N_f$ expansion one does not need the coupling constant renormalization; only the wave function renormalization remains. This means that the coupling is not running.

In the second order one again has the same diagrams as in a scalar theory but with vanishing triangles. The renormalization constant in the second order is also essentially simplified compared to the scalar case and looks like

$$Z_1 = 1 + \frac{1}{\varepsilon N_f} \frac{Ah}{1+h} + \frac{1}{\varepsilon^2 N_f^2} \frac{1}{2} \frac{A^2 h^2}{(1+h)^2} + O\left(\frac{1}{\varepsilon N_f^2}\right). \quad (6)$$

As explained in [I] the leading pole term $\sim 1/\varepsilon^2 N_f^2$ in (6) can be evaluated alternatively via the pole equations [12] from the $1/\varepsilon N_f$ one with the same result.

Like in the scalar case [I] the original dimensionful coupling e is not an expansion parameter anymore, but plays a role of a mass and is multiplicatively logarithmically renormalized. The leading order diagrams are shown in Fig.2.

Figure 2: The first order diagrams giving a contribution to the $1/e^2$ renormalization in the $1/N_f$ expansion

They give the following contribution:

$$Diag.a \Rightarrow \frac{h^2}{\varepsilon N_f (1+h)^2} F, \quad Diag.b \Rightarrow \frac{h^2}{\varepsilon N_f (1+h)^2} E, \quad Diag.c \Rightarrow 0, \quad (7)$$

$$F = \frac{\Gamma(D+1)(D/2-1)(D-1)^2(2-D/2)}{2^{D/2+1}\Gamma(2-D/2)\Gamma(D/2+2)\Gamma^2(D/2)}, \quad E = -\frac{D^2 + D/2 - 9}{D/2(D/2-1)(D-1)} F.$$

So one has

$$Z_{1/e^2} = 1 - \frac{1}{\varepsilon N_f} \left(\frac{(F+E)h^2}{(1+h)^2} \right) + O\left(\frac{1}{N_f^2}\right). \quad (8)$$

The solution of the RG equation for $1/e^2$ with fixed h gives the momentum dependence of e^2

$$\frac{1}{e^2} = \frac{1}{e_0^2} \left(\frac{p^2}{p_0^2} \right)^\gamma, \quad (9)$$

with the anomalous dimension

$$\gamma = \frac{\Gamma(D)(D-1)(D/2-2)(D-3)(D+2)(D-6)}{2^{D/2+1}\Gamma(D/2+2)\Gamma^2(D/2)\Gamma(2-D/2)N_f} \frac{h^2}{(1+h)^3}.$$

The sign of γ depends on D . For $D = 5, 7$ $\gamma > 0$, for $D = 9$ $\gamma < 0$ and then alternates with every odd D . Notice that eq.(9) reminds the power law behaviour of the initial coupling in extra dimensions within the Kaluza-Klein approach [13].

3 QCD

3.1 The effective Lagrangian

Consider now a non-Abelian theory. Here one has some novel features due to the presence of the triple and quartic gauge vertices and the ghost fields. Similar to (1) we write down the Lagrangian for the gauge fields and N_f fermions as

$$\mathcal{L} = -\frac{1}{4}(F_{\mu\nu}^a)^2 - \frac{1}{2\alpha}(\partial_\mu A_\mu^a)^2 + i\bar{\psi}_i \hat{\partial} \psi_i - m\bar{\psi}_i \psi_i + \frac{g}{\sqrt{N_f}}\bar{\psi}_i \hat{A}^a T^a \psi_i + \partial_\mu \bar{c}^a D_\mu c_a,$$

where

$$F_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a + \frac{g}{\sqrt{N_f}}f^{abc}A_\mu^b A_\nu^c, \quad D_\mu = \partial_\mu + \frac{g}{\sqrt{N_f}}[A_\mu, \]$$

Like in QED we choose the Landau gauge and sum up the fermion bubble diagrams into the denominator of the gauge field propagator

$$G_{\mu\nu}^{ab} = -\frac{i\delta^{ab}}{p^2} \frac{(g^{\mu\nu} - \frac{p^\mu p^\nu}{p^2})}{1 + g^2 f(D)(-p^2)^{D/2-2}}, \quad (10)$$

where the coefficient $f(D)$ differs from the Abelian case only by the color factor $T(R)$

$$f(D) = \frac{\Gamma^2(D/2)\Gamma(2-D/2)}{2^{[D/2]-1}\Gamma(D)\pi^{D/2}}T(R)$$

and again we put $m = 0$ for simplicity.

In the non-Abelian case, contrary to the Abelian one one has the triple and quartic self-interaction of the gauge fields. These vertices, which are suppressed by $1/\sqrt{N_f}$ and $1/N_f$, respectively, obtain loop corrections of the same order in $1/N_f$. The effective vertices in the leading order are given by the diagrams shown in Fig. 3 and 4.

Figure 3: The diagrams giving a contribution to the A^3 term in the zeroth order of the $1/N_f$ expansion

Figure 4: The diagrams giving a contribution to the A^4 term in the zeroth order of the $1/N_f$ expansion

Thus, besides the modification of the gauge propagator one has the modified vertices. The effective Lagrangian in the case of vertices is not given by a simple local expression due to complexity of the loop diagrams. So we keep it in the form of the diagrams which have to be evaluated in integer dimension. Due to the rules of dimensional regularization they are finite for any odd D , otherwise one has to redefine them. What is crucial, however, is that there are only three diagrams which have to be redefined. Hence, after rescaling the gauge field $A_\mu \rightarrow A_\mu/g$ one obtains the following effective Lagrangian:

$$\begin{aligned} \mathcal{L}_{eff} = & -\frac{1}{4g^2}(F_{\mu\nu}^a)^2 - \left(\text{diagram 1} + \text{diagram 2} + \text{diagram 3} \right) \\ & - \frac{1}{2\alpha g^2}(\partial_\mu A_\mu^a)^2 + i\bar{\psi}_i \hat{\partial} \psi_i - m\bar{\psi}_i \psi_i + \frac{1}{\sqrt{N_f}} \bar{\psi}_i \hat{A}^a T^a \psi_i + \partial_\mu \bar{c}^a D_\mu c_a, \end{aligned} \quad (11)$$

Notice that dimensionful coupling g drops from all terms except for the first one and is not an expansion parameter anymore.

Calculating the degree of divergence after summing up the diagrams of the zeroth order, similar to the scalar case and QED, one has only four types of logarithmically divergent diagrams: the fermion and the ghost propagators, the fermion-gauge-vertex and ghost-gauge-ghost vertex. The gauge propagator as well as pure gauge vertices are finite and may contain only divergent subgraphs.

The next step is the introduction of a dimensionless coupling h . Here one should be accurate since this coupling enters not only into the triple gauge-fermion vertex, but due to the gauge invariance should be present in gauge and gauge-ghost vertices. It should be the same in all three of them. In the case of a gauge theory, the coupling h enters the gauge transformation and acts as a gauge charge of the fermion and gauge fields.

When constructing the Feynman diagrams, one reproduces the one-loop cycles that are already present in the effective Lagrangian (12) but with additional factors h . In the scalar or QED case, this happened only for the propagator, but here it is also true for the vertices. As a result, the final expression for the effective Lagrangian takes the form

$$\begin{aligned} \mathcal{L}_{eff} = & -\frac{1}{4g^2}(F_{\mu\nu}^a)^2 - \left(\text{diagram 1} + \text{diagram 2} + \text{diagram 3} \right) (1+h) \\ & - \frac{1}{2\alpha g^2}(\partial_\mu A_\mu^a)^2 + i\bar{\psi}_i \hat{\partial} \psi_i - m\bar{\psi}_i \psi_i + \frac{h}{\sqrt{N_f}} \bar{\psi}_i \hat{A}^a T^a \psi_i + \partial_\mu \bar{c}^a D_\mu c_a, \end{aligned} \quad (12)$$

where

$$F_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a + \frac{\sqrt{h}}{\sqrt{N_f}} f^{abc} A_\mu^b A_\nu^c, \quad D_\mu c_a = \partial_\mu c_a + \frac{\sqrt{h}}{\sqrt{N_f}} f^{abc} A_\mu^b c^c.$$

3.2 Properties of the $1/N_f$ expansion

Consider now the leading order calculations. We start with the $1/N_f$ terms for the fermion and the triple fermion-gauge-fermion vertex. The diagrams are shown in Fig.5. The first two are the same as in QED. The third diagram contains new effective vertex which includes the usual triple vertex and the fermion triangle. The usual vertex does not give a contribution since it is finite by a simple power counting. At the same time, the fermion triangle is momentum dependent and the resulting diagram is logarithmically divergent.

Figure 5: The leading order diagrams giving a contribution to the ψ field propagator and the triple vertex in $1/N_f$ expansion

Calculating the singular parts of the diagrams of Fig.5 in dimensional regularization with $D' = D - 2\varepsilon$ one finds

$$Diag.a \Rightarrow \frac{1}{\varepsilon N_f} \frac{h}{1+h} A, \quad Diag.b \Rightarrow \frac{1}{\varepsilon N_f} \frac{h}{1+h} B, \quad Diag.c \Rightarrow \frac{1}{\varepsilon N_f} \frac{h}{1+h} C, \quad (13)$$

$$A = -\frac{\Gamma(D)(D-1)(2-D/2)C_F}{2^{D/2}\Gamma(2-D/2)\Gamma(D/2+1)\Gamma^2(D/2)T}, \quad B = -\frac{C_F - C_A/2}{C_F} A, \quad C = -\frac{(1-D/2)C_A}{2(2-D/2)C_F} A,$$

which is again in agreement with [14]. Notice that the third diagram is proportional to $h/(1+h)$ instead of $h^2/(1+h)^2$ as in the scalar case. The reason is that now we have an effective triple gauge vertex proportional to $\sqrt{h}(1+h)$ instead of $\sqrt{h}$ that cancels one factor of $h/(1+h)$.

Therefore, in the leading order in the $1/N_f$ expansion the renormalization constants take the form

$$Z_2^{-1} = 1 - \frac{1}{\varepsilon N_f} \frac{Ah}{(1+h)}, \quad (14)$$

$$Z_1 = 1 - \frac{1}{\varepsilon N_f} \frac{(B+C)h}{(1+h)}, \quad (15)$$

$$Z_h = Z_1^2 Z_2^{-2} = 1 - \frac{1}{\varepsilon N_f} \frac{2(A+B+C)h}{(1+h)}. \quad (16)$$

To check the gauge invariance, we calculated the renormalization of the coupling through the gauge-ghost interaction. The leading diagrams are shown in Fig.6.

Figure 6: The leading order diagrams giving a contribution to the ghost field propagator and the triple vertex in $1/N_f$ expansion

Calculating the singular parts of the diagrams in dimensional regularization one finds

$$Diag.a \Rightarrow \frac{1}{\varepsilon N_f} \frac{h}{1+h} A', \quad Diag.b \Rightarrow \frac{1}{\varepsilon N_f} \frac{h}{1+h} B', \quad Diag.c \Rightarrow \frac{1}{\varepsilon N_f} \frac{h}{1+h} C',$$

$$A' = -\frac{\Gamma(D)(D-1)C_A}{2^{D/2+1}\Gamma(2-D/2)\Gamma(D/2+1)\Gamma^2(D/2)T}, \quad B' = 0, \quad C' = 0, \quad (17)$$

which gives the following renormalization constants in the ghost sector

$$\tilde{Z}_1 = 1, \quad (18)$$

$$\tilde{Z}_2^{-1} = 1 - \frac{1}{\varepsilon N_f} \frac{A'h}{1+h}, \quad (19)$$

$$Z_h = \tilde{Z}_1^2 \tilde{Z}_2^{-2} = 1 - \frac{2}{\varepsilon N_f} \frac{A'h}{1+h}. \quad (20)$$

One can see that the following relation holds:

$$A + B + C = A' + B' + C', \quad (21)$$

which follows from the gauge invariance.

We look now at the next-to-leading order to compare it with the scalar case. The corresponding diagrams for the fermion propagator are shown in Fig.7. They require some explanation. The first line of diagrams in Fig.7 is obtained from the one-loop diagrams of Fig.5 by inserting into the vertex or the fermion line of the one-loop divergent subgraphs from Fig.5. For example, the diagram *d* in Fig.7 is the diagram *a* from Fig.5 with divergent one-loop subgraph *c* from Fig.5 substituted instead of the initial vertex. The second line of the diagrams in Fig.7 is obtained from the "forbidden" diagram of Fig.8 by inserting the same one-loop divergent subgraphs from Fig.5. The diagram *e* is the diagram of Fig.8 with insertion of the subgraph *a* from Fig.5 into the fermion line (see Fig.9) and the diagram *g* comes from the insertion of the subgraph *c* from Fig.5 instead of one of the vertices in the fermion loop (see Fig.10).

Figure 7: The second order diagrams giving a contribution to the fermion propagator in the $1/N_f$ expansion

Figure 8: The "forbidden" loop diagram

Figure 9: The diagram *e* from Fig.7 as a result of insertion of the diagram *a* from Fig.5 into the fermion line.

Figure 10: The diagram *g* from Fig.7 as a result of insertion of the diagram *c* from Fig.5 instead of one of the vertices in the diagram from Fig.8.

All these diagrams are double logarithmically divergent, i.e., contain both single and double poles in dimensional regularization. We calculated the leading double poles after subtraction of the divergent subgraphs, i.e., performed the R' -operation. The answer is:

$$Diag.a \Rightarrow -\frac{1}{\varepsilon^2 N_f^2} \frac{A^2 h^2}{2(1+h)^2}, \quad Diag.b \Rightarrow -\frac{1}{\varepsilon^2 N_f^2} \frac{AB h^2}{(1+h)^2}, \quad Diag.c \Rightarrow -\frac{1}{\varepsilon^2 N_f^2} \frac{A^2 h^2}{(1+h)^2},$$

$$\begin{aligned}
\text{Diag.d} &\Rightarrow -\frac{1}{\varepsilon^2 N_f^2} \frac{ACh^2}{(1+h)^2}, & \text{Diag.e} &\Rightarrow \frac{1}{\varepsilon^2 N_f^2} \frac{2A^2h^3}{3(1+h)^3}, \\
\text{Diag.f} &\Rightarrow \frac{1}{\varepsilon^2 N_f^2} \frac{2ABh^3}{3(1+h)^3}, & \text{Diag.g} &\Rightarrow \frac{1}{\varepsilon^2 N_f^2} \frac{2ACH^3}{3(1+h)^3}.
\end{aligned} \tag{22}$$

We performed also the calculation for the fermion-gauge-fermion vertex but do not present the diagram-by-diagram result because of the lack of space and give only the final answer.

Having all this in mind we come to the final expressions for the Z factors in the second order of the $1/N_f$ expansion in the fermion sector:

$$\begin{aligned}
Z_1 = & 1 - \frac{1}{\varepsilon N_f} \frac{(B+C)h}{1+h} + \frac{1}{\varepsilon^2 N_f^2} \left(\frac{3}{2} \frac{(B+C)^2 h^2}{(1+h)^2} + \frac{A(B+C)h^2}{(1+h)^2} \right. \\
& \left. - \frac{2}{3} \frac{(B+C)^2 h^3}{(1+h)^3} - \frac{2}{3} \frac{A(B+C)h^3}{(1+h)^3} \right) + O\left(\frac{1}{\varepsilon N_f^2}\right),
\end{aligned} \tag{23}$$

$$\begin{aligned}
Z_2^{-1} = & 1 - \frac{1}{\varepsilon N_f} \frac{Ah}{1+h} + \frac{1}{\varepsilon^2 N_f^2} \left(\frac{3}{2} \frac{A^2 h^2}{(1+h)^2} + \frac{A(B+C)h^2}{(1+h)^2} \right. \\
& \left. - \frac{2}{3} \frac{A(A+B+C)h^3}{(1+h)^3} \right) + O\left(\frac{1}{\varepsilon N_f^2}\right).
\end{aligned} \tag{24}$$

The same calculation in the ghost sector gives

$$\tilde{Z}_1 = 1, \tag{25}$$

$$\tilde{Z}_2^{-1} = 1 - \frac{1}{\varepsilon N_f} \frac{A'h}{1+h} + \frac{1}{\varepsilon^2 N_f^2} \left(\frac{3}{2} \frac{A'^2 h^2}{(1+h)^2} - \frac{2}{3} \frac{A'(A+B+C)h^3}{(1+h)^3} \right) + O\left(\frac{1}{\varepsilon N_f^2}\right) \tag{26}$$

Notice the absence of the ghost-gauge-ghost vertex renormalization.

The final second order expression for the coupling renormalization calculated in both ways having in mind relation (21) is

$$Z_h = 1 - \frac{1}{\varepsilon N_f} \frac{2(A+B+C)h}{1+h} + \frac{1}{\varepsilon^2 N_f^2} \left(4 \frac{(A+B+C)^2 h^2}{(1+h)^2} - \frac{4}{3} \frac{(A+B+C)^2 h^3}{(1+h)^3} \right) + O\left(\frac{1}{\varepsilon N_f^2}\right). \tag{27}$$

Like in the scalar and QED case, one can also calculate the renormalization of the original coupling g^2 . The leading order diagrams are shown in Fig. 11 which give the following singular parts like in [14]

Figure 11: The first order diagrams giving a contribution to the $1/g^2$ renormalization in $1/N_f$ expansion

$$\begin{aligned}
\text{Diag.a} &\Rightarrow \frac{1}{\varepsilon N_f} \frac{h^2}{(1+h)^2} F, \quad \text{Diag.b} \Rightarrow \frac{1}{\varepsilon N_f} \frac{h^2}{(1+h)^2} E, \\
\text{Diag.c} &\Rightarrow \frac{1}{\varepsilon N_f} \frac{h^2}{(1+h)^2} G, \quad \text{Diag.d} \Rightarrow \frac{1}{\varepsilon N_f} \frac{h^2}{(1+h)^2} H, \\
F &= \frac{\Gamma(D+1)(D/2-1)(D-1)^2(2-D/2)C_F}{2^{D/2+1}\Gamma(2-D/2)\Gamma(D/2+2)\Gamma^2(D/2)T(R)}, \quad E = -\frac{D^2+D/2-9}{D/2(D/2-1)(D-1)} \frac{C_F-C_A/2}{C_F} F, \\
G &= \frac{4(D/2)^6-6(D/2)^5+18(D/2)^4-67(D/2)^3+85(D/2)^2-19D+6}{2(D-1)^2(1-D/2)^2(2-D/2)D} \frac{C_A}{C_F} F, \\
H &= \frac{D^3-D^2/2-2D+1}{D(1-D/2)(2-D/2)(D-1)^2} \frac{C_A}{C_F} F.
\end{aligned} \tag{28}$$

The corresponding renormalization constant looks like

$$Z_{1/g^2} = 1 - \frac{1}{\varepsilon N_f} \frac{(F+E+G+H)h^2}{(1+h)^2}. \tag{29}$$

3.3 Renormalization group in $1/N_f$ expansion

Having these expressions for the Z factors one can construct the coupling constant renormalization and the corresponding RG functions. One has as usual in dimensional regularization

$$h_B = (\mu^2)^\varepsilon h Z_1^2 Z_2^{-2} = (\mu^2)^\varepsilon \left(h + \sum_{n=1}^{\infty} \frac{a_n(h, N_f)}{\varepsilon^n} \right), \tag{30}$$

$$Z_i = 1 + \sum_{n=1}^{\infty} \frac{c_n^i(h, N_f)}{\varepsilon^n}, \tag{31}$$

where the first coefficients a_n and c_n^i can be deduced from eqs.(23,24,25,26).

This allows one to get the anomalous dimensions and the beta function defined as

$$\gamma(h, N_f) = -\mu^2 \frac{d}{d\mu^2} \log Z = h \frac{d}{dh} c_1, \tag{32}$$

$$\beta(h, N_f) = 2h(\gamma_1 + \gamma_2) = (h \frac{d}{dh} - 1) a_1. \tag{33}$$

With the help of eqs.(23,24) one gets in the leading order of the $1/N_f$ expansion

$$\gamma_2(h, N_f) = -\frac{1}{N_f} \frac{Ah}{(1+h)^2}, \quad \gamma_1(h, N_f) = -\frac{1}{N_f} \frac{(B+C)h}{(1+h)^2}, \tag{34}$$

$$\tilde{\gamma}_2(h, N_f) = -\frac{1}{N_f} \frac{A'h}{(1+h)^2}, \quad \tilde{\gamma}_1(h, N_f) = O\left(\frac{1}{N_f^2}\right), \tag{35}$$

$$\beta(h, N_f) = -\frac{1}{N_f} \frac{2(A+B+C)h^2}{(1+h)^2}, \tag{36}$$

It is instructive to check the pole equations [12] that express the coefficients of the higher order poles in ε of the Z factors via the coefficients of a simple pole. For Z_2^{-1} one has, according to (24),

$$c_1(h, N_f) = -\frac{1}{N_f} \frac{Ah}{1+h}, \quad (37)$$

$$c_2(h, N_f) = \frac{1}{N_f^2} \left(\frac{3}{2} \frac{A^2 h^2}{(1+h)^2} + \frac{A(B+C)h^2}{(1+h)^2} - \frac{2}{3} \frac{A(A+B+C)h^3}{(1+h)^3} \right). \quad (38)$$

At the same time, the coefficient c_2 can be expressed through c_1 via the pole equations as

$$h \frac{dc_2}{dh} = \gamma_2 c_1 + \beta \frac{dc_1}{dh}, \quad (39)$$

Integrating this equation one gets for c_2 the expression coinciding with (38) which was obtained by direct diagram evaluation.

We have also checked the pole equations for the renormalized coupling. From eq.(27) one gets the coefficients of the coupling constant renormalization factor Z_h

$$a_1(h, N_f) = -\frac{1}{N_f} \frac{2(A+B+C)h^2}{1+h}, \quad (40)$$

$$a_2(h, N_f) = \frac{1}{N_f^2} \left(4 \frac{(A+B+C)^2 h^3}{(1+h)^2} - \frac{4}{3} \frac{(A+B+C)^2 h^4}{(1+h)^3} \right). \quad (41)$$

At the same time, from the pole equations one has

$$(h \frac{d}{dh} - 1)a_n = \beta \frac{da_{n-1}}{dh}. \quad (42)$$

The coefficient a_2 evaluated in this way coincides with (41).

Equation (27) gives us the sign of the beta function. In the leading order one has

$$\frac{dh}{dt} = \beta(h) = \frac{\Gamma(D)(D-1)C_A}{2^{D/2}\Gamma(2-D/2)\Gamma(D/2+1)\Gamma^2(D/2)N_f T} \frac{h^2}{(1+h)^2}, \quad (43)$$

which means that $\beta(h) < 0$ for $D = 5$, $\beta(h) > 0$ for $D = 7$ and then alternates with D .

Notice that in QCD, contrary to QED, all Feynman diagrams contain group factors so that the actual expansion parameter becomes N_c/N_f , thus requiring that this ratio is small. Of course, in non-Abelian theories the $1/N_c$ expansion would be preferable, since it accumulates the interactions of the gauge fields, however, in this case already the lowest approximation consists of all planar diagrams and is not known [15].

4 Conclusion

We conclude that in higher dimensional gauge theories like in the scalar case despite formal non-renormalizability it is possible to construct renormalizable $1/N_f$ expansion which obeys all the rules of a usual perturbation theory. The expansion parameter is

dimensionless, the coupling is running logarithmically, all divergencies are absorbed into the renormalization of the wave function and the coupling. The original dimensionful coupling plays a role of mass and is renormalized multiplicatively. Expansion over this coupling is singular and creates the usual nonrenormalizable terms.

Properties of the $1/N_f$ expansion do not depend on the space-time dimension if it is odd. In even dimension our formulas after subtraction contain a logarithm which creates some technical problems in calculations. We plan to consider these theories later.

There is one essential point that we omitted in our discussion, namely, the analytical properties of the gauge field propagator and the unitarity of a resulting theory. As one can see from eqs.(2) and (10), the propagator of the gauge field contains a cut starting from $p^2 = 0$ in the massless case or from $4m^2$ in the massive one. It may also contain poles in complex momentum plane. This imposes the question about unitarity of a resulting theory.

The unitarity of such an expansion was shown in [8] at the tree level. In the case of loops, one can show that all the cuts imposed on diagrams when applying Cutkosky rules [16] in any order of perturbation theory lead to the usual asymptotic states on the mass shell and no new states appear. From this point of view the theory remains unitary in physical space. The scattering amplitudes also behave safely decreasing with momenta, thus do not violating the unitarity requirement.

The only source of conceptual problem is the presence of poles in the propagator in the complex momentum plane. They may appear in the Euclidean region for negative k^2 (as in D=5) or for complex k^2 (as in D=7). In the first case, they create a problem when integrating over Euclidean momenta and one might take the integrals in a sense of a principle value, while in the second case this does not happen, but in both the cases the presence of this type of poles might be interpreted as appearance of new (ghost) states. Note, however, that the form of a dressed propagator is not specific for the $1/N_f$ expansion, but is typical of any perturbation theory. For instance, in the usual QED or any other renormalizable theory the dressed propagator has the same form and may obtain poles in the momentum plane (the Landau pole is an example). This is incompatible with the Källen-Lehmann representation leading to a non-positive spectral function [17] or to a negative contribution from pole terms, which signals negative norm states exist.

A usual way to avoid this problem is to consider the effective theory at low momenta below the Landau pole assuming that the situation is improved in a proper higher dimensional theory. Indeed, in the four dimensional QED the Landau pole exists at the energies above the Planck scale and one can safely use QED at lower momenta. In our case, however, due to power like behaviour it happens much earlier and severely constrains the region of validity of this theory.

There are several attempts to build renormalizable effective quantum gravity using a kind of $1/N$ expansion [18], where the role of an expansion parameter $1/N$ is played by the number space-time dimensions. The large D limit in this case is very similar to the large N_c planar diagram limit in the Yang-Mills theory considered by 't Hooft [15]. The technique similar to the $1/N_f$ expansion is used also in [19], though no large parameter appears. The author, as in [20], sums up the soft graviton corrections to the propagators of the scalar field to get an improved propagator which decreases faster than any power

of $|k^2|$. Though this partial resummation is similar to our $1/N$ expansion, the absence of an expansion parameter does not justify, to our mind, the selected set of diagrams. From this point of view the $1/N$ expansion is more consistent and contains the guiding line for such a selection.
